A Direct, Concise and Stereoselective Formal Synthesis of Platensimycin

by

Heriberto Rivera Jr., B.Sc.

Dissertation

Presented to the Faculty of the Graduate School of

The University of Texas at Austin

in Partial Fulfillment

of the Requirements

for the Degree of

Doctor of Philosophy

The University of Texas at Austin

December 2011

Dedication

To my mother, whose love, hard work, sacrifice and dedication has made everything possible.

Acknowledgements

Mrs. Maria Rivera: There are not enough words to describe what you have done for me.

Mr. Roberto Rivera, Mr. Francisco Rivera and Ms. Brenda Rivera: Your love and sacrifice will never be forgotten.

Ms. Lily Abbott: Thank you for helping me close a chapter in my life and helping me start a new one. I love you very much.

Dr. Ryan Littich: I am happy to consider you part of my family, brother.

Mr. Justin Dragna: Hermano, thank you for keeping me sane.

Mr. Dan Propheter: Shee-koo-koo-keek.

Mr. Chris Grant: Thank you for being a good friend and helping me become a better chemist.

Mr. Fernando Pedraza: Your advice hasn't failed me yet. Thanks for everything.

Mr. Alec Brozell: You rank as funniest man in my book.

Mrs. Negar Garizi: Your guidance was invaluable and your friendship irreplaceable.

Mr. David Hardin: You are truly an amazing teacher. Thank you for pushing me to my limits.

Mrs. Jackie Hester: Thank you for being a great teacher and wonderful friend.

Dr. Elizabeth Komives: Thank you for helping me find my path. I will always remember your generosity and kind heart.

Dr. Philip Magnus: Thank you for helping me grow as a scientist and as a person. I doubt I could have asked for a better mentor.

A Direct, Concise and Stereoselective Formal Synthesis of Platensimycin

Publication No. _____

Heriberto Rivera Jr., Ph.D.

The University of Texas at Austin, 2011

Supervisor: Philip D. Magnus

Herein we describe the synthesis of (\pm) platensimycin, a potent antibiotic against gram-positive bacteria. The first chapter reviews (\pm) platensimycin's isolation, biological profile and previously reported studies relevant to the area. The second chapter describes our initial efforts to synthesize (\pm) platensimycin. The third chapter accounts our second generation synthesis and its completion. The fourth chapter entails the experimental details of the important compounds in our synthesis.

Chapter 1: Platensimycin: The New Antibiotic

1.1 Introduction

The increasing number of antibiotic resistant bacteria and lack of new antibiotics, has greatly increased the need for researchers to make new discoveries. In 2006, Merck Laboratories discovered two new natural products with antibacterial properties, platensimycin **1** and platencin **2** (**Figure 1.1.1**).¹ They are produced by *Streptomyces platensis*, a bacterium discovered in soil samples from South Africa and Spain. It was determined that both platensimycin and platencin function as potent inhibitors in cellular lipid biosynthesis, in a novel mode of action. Furthermore, they displayed great selectivity and low cytotoxic properties.

Figure 1.1.1: Structures of Platensimycin and Platencin

To complement its appealing antibacterial properties and novel mode of action, platensimycin also has a very unusual molecular architecture. It consists of two major fragments, a tetracyclic acid enone core and a 3-amino-2,4 hydroxy benzoic side chain (**Figure 1.1.2**). Although the disconnection at the amide bond is obvious, developing a

strategy for the synthesis of the individual components constitutes a synthetic challenge. Thus, it has been the focus of many synthetic groups over the last 5 years.

Figure 1.1.2: (A) tetracyclic acid enone core (B) amino benzoic acid side chain

1.2 Isolation and Structural Determination

Platensimycin was discovered by the use of new high throughput screening method developed at Merck.² This method employs an antisense differential sensitivity technique. Once it was determined that platensimycin was produced by *Streptomyces platensis*, fermentation was implemented to gain access to greater amounts of the natural product. The resulting broth was purified using a two-step process using Amberchrome and reverse phase HPLC chromatography.

The molecular formula was determined using HRESIFTMS and corroborated using ¹³CNMR. Various ¹HNMR techniques (NOSEY, NOED, HMBS) were used to help determine the molecular structure and relative stereochemistry. Finally, crystallographic analysis of a 6'-bromo platensimycin (**Figure 1.2.1**) allowed for the unambiguous assignment of structure and absolute stereochemistry.³

Figure 1.2.1: 6'-bromo platensimycin

1.3 Biological Profile

Discoveries in the realm of antibiotics in the last 50 years have been few and with limited success. Two of these in particular are cerulenin and thiolactomycin which target the FabF enzyme, a target for antibacterial agents for the past 30 years.⁴ Fab F is an elongation condensing enzyme, a key component in fatty acid biosynthesis that is highly conserved among many important bacteria. As such, a successful drug designed to specifically bind FabF will make a potent antibiotic and allow it to be used for a wide range of pathogens.

Through high throughput screening techniques and *in vitro* experiments it was determined that platensimycin inhibited *S. aureus* FabF and *Escherichia coli* FabF/B enzymes with IC_{50} values of 48 and 160 nM, respectively. These inhibition concentrations were very promising when compared to IC_{50} values for cerulenin and thiolactomycin which range from 1.5-13 $\mu\text{g/mL}$. Astonishing results were also obtained for MRSA (Methicillin-resistant *Staphylococcus aureus*) and VRE (Vancomycin-Resistant *Enterococci*) with MIC values of .1-1 $\mu\text{g/mL}$. Furthermore, whole-cell labeling experiments show that platensimycin specifically binds to *S. aureus* (without interfering with DNA, RNA, protein, or cell wall biosynthesis) with concentrations up to 500 $\mu\text{g/mL}$.¹

Promising results were also obtained in *in vivo* experiments using mice. Mice infected with *S. aureus*, showed in a decrease of 4-5 log reduction of infection after 24 hours with treatment of platensimycin (100 $\mu\text{g h}$). It is also important to note that no toxicity was observed in this particular case nor was it observed in examples where the mice were treated for elongated periods of time, up to 8 days.¹

The major drawback of platensimycin is the need for continuous administration in order to be effective. This has spurred a significant interest in the synthesis of platensimycin analogs. To date, none of the analogs have shown improved efficacy upon administration.^{5,6}

Platensimycin's potency and selectivity have made it an ideal candidate for more extensive research. Although it suffers from a poor pharmacokinetic profile, it still has the potential to have a major impact in the antibiotic arena. With many promising attributes, platensimycin has become a prime target for scientists.

1.4 Previous Syntheses

With an impressive pharmacological profile and complex molecular structure it is no surprise that platensimycin has been the focus of many synthetic groups, including our own. Since 2006 there have been two total syntheses^{7,8}, numerous formal syntheses^{9,10,11,12,13,14} and formation of platensimycin analogues.^{15,16} The proceeding sections will focus on key syntheses. The first will be the initial synthesis by Nicolaou, which has been the foundation for nearly all of the formal syntheses published. This will be succeeded by the work from the Mulzer group, which employs a similar strategy to our own. Lastly, I will briefly address the key reactions in the asymmetric syntheses of platensimycin.

1.4.1 The Nicolaou Synthesis

In 2006 the Nicolaou group published the first total synthesis of platensimycin.⁷ They started with commercially available ethoxy enone **3** and performed a sequential alkylation to give compound **4** (**Scheme 1.4.1**). Compound **4** was reduced, hydrolyzed under acidic conditions and the allylic alcohol was re-protected to produce enone **5**. Cylcoisomerization of compound **5** using a ruthenium catalyst gave spirocycle **6**, in a 1:1 distereomeric ratio. They overcame this obstacle in subsequent work. Saegusa oxidation produced dienone **7**, which upon exposure to acid gave aldehyde **8**. Radical cyclization with SmI_2 afforded compound **9** in a 2:1 ratio favoring the desired diastereomer. Even though they were able to obtain the desired isomer as the major product they did so in poor yield (42% total yield). Next, compound **9** underwent an intramolecular cyclization to give compound **10**, the tetracyclic core of platensimycin. It is important to note that this compound is the target for all formal syntheses. Another set of sequential alkylations led to disubstituted enone **12**. Finally, olefin metathesis with Grubbs second generation catalyst and two subsequent oxidations gave carboxylic acid **15**. It was noted by the authors that more direct route could have been achieved using methyl acrylate instead of allyl bromide, but they were unable to obtain any conclusive results. With the first half of the platensimycin synthesized they directed their efforts toward the amino benzoic acid moiety.

Scheme 1.4.1: Synthesis of the tetracyclic acid enone core

The reaction scheme shows the synthesis of compounds **16**-**21** starting from 1,2-dihydroxybenzene derivatives.
 The first step involves the reduction of a nitro group (NO_2) to an amine (NHR) using H_2 and Pd/C catalyst (b).
 Subsequent steps include protection/deprotection of hydroxyl groups as MOM or Boc esters (c), esterification of carboxylic acids with methanol (d), and thermal cyclization at 205°C (e) to form the final products **16**-**21**.

a) NaH, MOMCl \rightarrow **16:** R = H; **17:** R = MOM
c) Boc_2O \rightarrow **18:** R = H; **19:** R = Boc
d) $n\text{BuLi}$, TMSCl; $n\text{BuLi}$, MeOC(O)CN \rightarrow
e) 205°C \rightarrow **20:** R = Boc; **21:** R = H

thermolysis to produce benzoic acid moiety **21**. An improved method for the synthesis of the trisubstituted benzoic acid chain was later developed by the Nicolaou group.

Scheme 1.4.3 Peptide coupling.

The Nicolaou group was able to achieve the synthesis of the tetracyclic core in 15 linear steps and the total synthesis of platensimycin in 22 overall steps. Although their strategy suffered from stereochemical issues and low yields in key transformations, they produced the inaugural synthesis of platensimycin which provided the foundation for all succeeding formal syntheses. Furthermore, they were able to complete the synthesis in a short number of steps which still rivals the latest syntheses.

1.4.2 The Mulzer Synthesis

In 2007 the Mulzer group published the formal synthesis of platensimycin.¹⁷ This was of special importance to us because it directly involved the strategy we had devised, specifically using dienone **25** as a key intermediate. Their synthesis began with tetralone **22**, which is commercially available and relatively inexpensive (**Scheme 1.4.4**). They took tetralone **22** and converted it to carboxylic acid **23** in three steps using previously published procedures. The resulting unsaturated carboxylic acid **23** was reduced using standard hydrogenative conditions to give carboxylic acid **24**. Carboxylic acid **24** was

Scheme 1.4.4: Formation of key intermediate **25**

converted to the acyl chloride and treated to TMS-diazomethane to give the beta-hydrazido ketone. Finally, the resulting diazoketone was treated with TFA to give dienone **25** in 59% yield over 3 steps.

Their end game started with a Grignard addition into the saturated ketone **25** to give tertiary alcohol **26** with both regio- and stereoselectivity albeit in low yield. (**Scheme 1.4.5**). Compound **26** was then brominated at the γ -position using NBS. The resulting brominated compound **27** possessed the appropriate stereochemistry for an intramolecular S_N2 displacement.

Figure 1.4.5 Completion of the Mulzer Synthesis

Upon treating bromide **27** with NaOMe in THF, the desired ether was formed to give tetracycle **28**. Compound **28** underwent global reduction upon exposure to Crabtree's Catalyst to produce saturated ketones **29** and **30**, giving a 1.3:1 distereomeric ratio. This step suffers from poor stereoselectivity and from a low yield. Furthermore it seems counterproductive to perform a global reduction only to have to reoxidize to the appropriate oxidation level. Finally, taking reduced product **29** and treating it to oxidative conditions gave mono-oxidized product **10** in 60% yield.

The Mulzer group was able complete the formal synthesis of platensimycin in 12 linear steps starting with commercially available materials. They devised a short and direct route to the tetracyclic core of platensimycin and did so in a protecting group free

fashion. Though the synthesis was efficient, it suffered from a few major drawbacks. First, the Grignard addition was low yielding, with an actual yield closer to 25%. The reduction itself also suffered from poor selectivity and low yield. Finally, as previously pointed out, it seems impractical to toggle between oxidation states (conversion of **28** to **10** in **Figure 1.4.5**).

1.3.3 Asymmetric Syntheses

In this section we will highlight the key steps, in chronological order, of the asymmetric syntheses of (-)-platensimycin. Before we go into detail on work not yet addressed, I will briefly state that both the Mulzer (2010)¹⁸ and Nicolaou (2009)^{19,20} groups were able to produce enantioselective syntheses. They performed key stereocontrolled reactions in the reduction of the unsaturated acid **23** and the cycloisomerization of compound **5**, respectively.

In 2007 the Yamamoto group published the second asymmetric synthesis of (-)-Platensimycin.²¹ Their strategy involved two key transformations in which they were able to enforce the desired stereochemistry (**Scheme 1.4.6**). The first reaction involved an Diels-Alder reaction with methyl acrylate and cyclopentadiene using a Brønsted acid assisted chiral Lewis acid (**34+35**). They obtained cycloadduct **33** in high yield and high enantioselectivity. The second step, coincidentally the final step of their synthesis, was a stereoselective intramolecular Michael addition of bicyclic compound **36**. They obtained the desired diastereomer **10** as the major product in good yield (80%).

Scheme 1.4.6: (a) Stereoselective Diels-Alder (b) Stereoselective Michael addition

The next body of work was published by the Corey group.²² The first reaction consists of an enantioselective conjugate addition of a 2-propenyl group into enone **37** using a rhodium catalyst (**Scheme 1.4.7**). The addition product was obtained in high yield and high enantioselectivity. The other step was a high pressure, rhodium catalyzed diastereoselective reduction of dienone **28**, which gave saturated ketone **29** in good yield.

Figure 1.4.7: (A) Enantioselective conjugate addition (B) Diastereoselective reduction

Matsuo and coworkers also took advantage of a stereoselective Diels-Alder reaction (**Scheme 1.4.8**).²³ They treated diene **40** with enone **39** to give bicyclic compounds **41** and **42** in 83% yield with 11:1 ratio in favor of the desired product.

Scheme 1.4.8: Matsuo's diastereoselective Diels-Alder reaction

Two years later the Lear²⁴ group and Canesi²⁵ groups published asymmetric syntheses. The Lear group utilized an organocatalyst in a diastereoselective reduction. They took dienone **43** and treated it to *tert*-butyl D-phenylalanine then exposed it to sequential Hantzsch and Pd/C based reductions to produce ketones **29** and **30** (**Scheme 1.4.9**). Although they were able to isolate compounds **10** and **44**, they observed large amounts of degradation upon purification, so the crude was directly submitted to the second reduction.

Scheme 1.4.9: Sequential reductions to afford compound 30 enantioselectively

The Canesi group utilized a stereoselective oxidative Prins-Pinacol tandem process to transform compound **45** to spirocycle **46** in 64% yield over 2 steps (**Scheme 1.4.10**). This spirocycle is similar to intermediate **6** in the Nicolaou synthesis and the succeeding transformations mirror closely what was done in the Nicolaou synthesis to obtain enone **10**.

Scheme 1.4.10: Formation of spirocycle **46**

The latest asymmetric synthesis was published by the Nakada group which centered on an enantioselective catalytic asymmetric intramolecular cyclopropanation.²⁶ They synthesized α -diazosulfone **47** and subjected it to a chiral copper catalyst to produce cyclopropyl compound **48** in 72% yield (**Scheme 1.4.11**). This compound was elaborated to an intermediate in the Snider synthesis and eventually transformed to enone **10**.

Scheme 1.4.11 Enantioselective formation of cyclopropane **48**

Although these formal syntheses allowed for the asymmetric synthesis of (-)-platensimycin, they had many shortcomings. Devising an asymmetric strategy required many of these groups to add several steps, accept low yields and in some cases report comparable stereoselectivities. To date the Nicolaou asymmetric synthesis offers the best example of an asymmetric synthesis.

1.5 Conclusions

Platensimycin's potency, selectivity and molecular complexity have made it an appealing target for synthetic chemists. Though a multitude of syntheses had been published, we believed a more concise and direct route could be developed. In the following chapters we will describe our synthetic strategy of the platensimycin core.

Chapter 2: First Generation Synthesis

2.1 Introduction

Platensimycin is a potent antibiotic against gram-positive bacteria that was discovered in 2006 by Merck. Complementing its impressive biological profile is its molecular complexity. The unusual structural motif of platensimycin has aroused significant attention from the synthetic community. Although many syntheses have been published we felt that we could produce a more precise and stereospecific synthesis.

2.2 Synthetic Approach

We devised a strategy beginning with 6-methoxy-1-tetralone **22**. Tetralone **22** was chosen because it is both commercially available and inexpensive. Tetralone **22** is elaborated to carboxylic acid **24**. Carboxylic acid **24** is converted to dienone **25**, a compound that has been previously produced in gram scale.

The next phase of the synthesis begins with a Grignard addition into dienone **25** to give tertiary alcohol **26**. Dienone **26** is converted to dialkylated compound **49**, providing the appropriate oxidation level at the enone. Hydroboration and cyclization of compound **49** gives cyclic ether **50**. Hydrolysis of compound **50** would afford carboxylic acid **15**, thereby completing the formal synthesis. Successful execution of this route would provide the shortest route to the platensimycin core.

Scheme 2.2.1: Synthetic Approach

2.3 Background for the Dienone **25**

In the early 1970's Mander published a series of papers displaying the synthesis of various intermediates directed toward the formation of tetracyclic diterpenes.^{1,2,3,4} The structure that caught our attention was dienone **25** (**Figure 2.3.1**). It piqued our interest for various reasons. First, it contained all but one carbon in the carbocyclic framework of

Figure 2.3.1: Mander's Dienone **25** and Nicolaou's Enone **10**

enone **10**. Mander went on to show that compound **25** reacts stereoselectively upon treatment with sodium borohydride (**Figure 2.3.2**). These results lead us to believe that compound **25** treated with methyl Grignard could produce compound **10** on gram scale.

Figure 2.3.2: Examples of regioselectivity

2.4 Synthesis of Dienone 25

The synthesis of enone **25** began with the acylation of 6-methoxy-1-tetralone **22**.⁵ Tetralone **22** was added to a mixture of dimethyl carbonate and NaH and heated to provide α,β -ketoester **54** (**Scheme 2.2**). α,β -ketoester **54** was directly reduced to methyl ester **55**.⁶ The methyl ester was hydrolyzed to provide carboxylic acid **24** as an off white solid. Carboxylic acid **24** was produced in 84% yield over 3 steps and with a single purification. It is worthwhile noting that both the R- and S-enantiomers of acid **24** are available from the microbial reduction of 1-tetralone-2-carboxy ethyl esters.⁷ Hence, it is possible to execute this route asymmetrically.

Scheme 2.4.1: Synthesis of dienone **25**

Carboxylic acid **24** was converted to acyl chloride **56** upon treatment with thionyl chloride. Acyl chloride **56** was treated with freshly prepared diazomethane to give α -diazoketone **57**. The resulting mixture was exposed to TFA to give key intermediate **25**. Dienone **25** was obtained in 61% yield over three steps and with a single purification.

We were able to obtain dienone **25** in 6 steps, 1 less step than the Mulzer group, and in gram quantities. We were now situated to perform the Grignard addition.

2.5 Grignard Addition

As we were approaching this step in our synthesis, the Muzler work was published. Although they were fruitful in producing the tertiary alcohol **26**, it was reported as an ambiguous 71% yield (brsm = by recovered starting material, **Scheme 2.5.1**). It was no surprise that when Mulzer's conditions were used a paltry yield of 26% was obtained (**Scheme 2.5.1**). Thus, we set our efforts to improve this transformation.

Scheme 2.5.1: Mulzer's conversion of dienone **25** to tertiary alcohol **26**

We began exploring this transformation by choosing Grignard reagents with different halogen counteranions (**Table 2.5.1**). The differences between MeMgI, MeMgBr, and MeMgCl were minimal (Entry A-C). For quality purposes fresh solutions of MeMgBr and MeMgI were prepared but offered no advantage over the commercially available reagents (Entry D-E). The reactions performed with different solvents yielded unreacted starting material (Entry F-K). This was possibly due to solubility issues. The reactions were normally run at 0.3 M because it was determined this was the optimal reaction concentration (Entry A-C). However, using dimethyl ether or dimethoxy methane (DMM) required the reaction to be diluted to .03 M. We believe this huge decrease in reaction concentration was responsible for our results. Finally, varying the reaction temperature had little impact on the yield (Entry L). Having exhausted the

possible avenues utilizing different Grignard reagents we decided to test other methyl nucleophilic sources.

Entry	Grignard (1eq)	Temp (°C)	Solvent	Time (h)	Yield (%)
A	MeMgI	-78	THF	4	25
B	MeMgBr	-78	THF	4	24
C	MeMgCl	-78	THF	4	28

J	MeMgBr	-78	DMM	4	sm
K	MeMgCl	-78	DMM	4	sm
L	MeMgI	-78 to rt	THF	4	25

Table 2.5.1: Grignard Addition

The reaction conditions from the Grignard addition were maintained with the exception of the nucleophile source (**Table 2.5.2**). Using MeLi gave a 13% yield (Entry A). All other reagents failed to produce any positive results (Entry B-E).^{8,9} When the reactions were run at 0 °C and allowed to warm to ambient temperature, only TiCl₃Me managed to give any of the desired product albeit in low yield (Entry F-H).^{10,11} Although this was a low yield, further reactions were performed using TiCl₃Me. When the reaction was run at higher temperatures or with an excess of the reagent, a multitude of unidentifiable compounds were obtained (Entry I,K). Changing the solvent resulted in recovered starting material (Entry J).

Entry	Reagent (1 eq)	Temp (°C)	Solvent	Time (h)	Yield (%)
A	MeLi	-78	THF	4	13
B	(CH ₃) ₂ CuLi	-78	THF	4	sm

Table 2.5.2: Use of different methylating sources

One thing that had caught our attention was that the experiments run with MeLi (**Table 2.5.2** Entry A,E). We were partially surprised to have not obtained the desired product at 0 °C. This led us to believe that a competition was occurring between the reagent acting as base instead of nucleophile. We devised a quick and easy experiment where dienone **25** was treated to previous conditions except that the reaction was quenched with D₂O instead of H₂O (**Scheme 2.5.2**). Deuterated compound **57** was isolated and the ¹H NMR indicated the incorporation of deuterium by the disappearance of the indicated proton. These results strongly suggested it was an issue of enolization versus addition.

Scheme 2.5.2: Deuterium exchange experiment

The issue of enolization versus addition is not without precedent. It has been shown that using CeCl_3 helps to deter the path of enolization and favor Grignard addition.¹² Although, how it actually impedes enolization is not completely understood. Reaching this conclusion, the experiments using Grignard reagents were re-run in the presence of CeCl_3 (**Table 2.5.3**). These reactions were run with 1 equivalent of CeCl_3 and at a 0.08 mM concentration. Running the reaction under previous conditions produced poor results. Increasing the reaction temperature had little to no effect with about 50% decrease in yield (Entry A-C). Preparing our own Grignard reagent gave similar results (Entry D). Increasing the reaction temperature had little to no effect (Entry F-H). In the instances where MeLi was used, only starting material was recovered

Entry	Grignard (1eq)	Temp (°C)	Solvent	Time (h)	Yield (%)
A	MeMgI	-78	THF	4	15

H	MeMgCl	-78-rt	THF	4	14
I	MeLi	-78-rt	THF	4	sm

Table 2.5.3: Grignard addition in the presence of CeCl_3

(E, I). We had reached major roadblock and had to seriously consider continuing this feat or accept the yields obtained from Mulzer's work.

We came up with one final idea before retreating; we would simply increase the equivalents of the Grignard reagent (**Table 2.5.4**). As the equivalents of MeMgCl were increased, the yield increased as well (Entry A-C). Eventually it was determined that best yield was obtained using 3 eq of MeMgCl (Entry C). A 61 % isolated yield of tertiary alcohol **26** represents almost a 250% increase in yield from the Muzler procedure (**Table 2.5.4**).

Entry	Grignard	Eq	Temp (°C)	solvent	Time (h)	Yield (%)
A	MeMgCl	1	-78	THF	4	28
B	MeMgCl	2	-78	THF	4	46
C	MeMgCl	3	-78	THF	4	61
D	MeMgCl	4	-78	THF	4	57
E	MeMgCl	5	-78	THF	4	55

Table 2.5.4: Increasing the amount of MeMgCl

These experiments were repeated with other Grignard reagents and MeLi but gave inferior results. Varying temperature and reaction times also failed to provide further improvement.

Ultimately, dienone **25** dissolved in THF and MeMgCl (3 eq.) was added to give tertiary alcohol **26** in 60% yield (**Scheme 2.5.3**).

Scheme 2.5.3: New found conditions for the formation of tertiary alcohol **26**

2.6 Alkylation

Now that the Grignard addition had been adequately solved, we continued with the subsequent sequence of alkylations. Dienone **26** was submitted to standard alkylating conditions to give α -methyl dienone **58** in good yield and without any trace of the germinal dimethylation product (**Scheme 2.6.1**).¹³

Scheme 2.6.1: Methylation of dienone **26**

The succeeding alkylation with methyl acrylate (MeA) was performed under similar conditions as the methyl addition but was unfruitful (**Table 2.6.1**, Entry A).¹⁴ Varying the conditions provided similar results. Increasing the equivalents of methyl acrylate or ^tBuOK resulted in recovered starting material (Entry B-D). Increasing the temperature from ambient temperature to 60 °C resulted in a mixture of unidentifiable compounds (Entry E). Utilizing triton-B, previously shown to affect the desired transformation, resulted in recovered starting material (Entry F).¹⁵ Similar experiments

were implemented using ethyl bromoacetate in lieu of methyl acrylate, but these conditions also failed to provide any positive results.

Scheme 2.6.2: Attempted alkylation of dienone **58**

Entry	Base	Base eq	Methyl Acrylate (eq)	Solvent	Temp (°C)	Time (h)	Yield (%)
A	<i>t</i> BuOK	2.2	1	<i>t</i> BuOH	rt	6	sm
B	<i>t</i> BuOK	2.2	2	<i>t</i> BuOH	rt	6	sm
C	<i>t</i> BuOK	2.2	5	<i>t</i> BuOH	rt	6	sm

F	K ₂ CO ₃ / Triton B (cat)	2.2	1	DCE	rt-reflux	12	sm

Table 2.6.1: Conditions for methyl acrylate alkylation of **58**

It was evident that the formation of the quaternary center was not going to be as straight forward as imagined. We believed that we might affect this transformation by simply reversing the order of alkylation. Dieneone **26** was treated to alkylating conditions but this proved to be an unfruitful endeavor (**Table 2.6.2**). Varying the amount of methyl acrylate had no effect (Entry A-C). When the reaction was heated, an inextricable mixture was obtained (Entry D). Lack of success led us to abandon the use methyl acrylate and seek a suitable alternative.

Scheme 2.6.3: Attempted alkylation with methyl acrylate

Entry	Base	MeA (eq)	Solvent	Temp (°C)	Time (h)	Yield (%)
A	<i>t</i> BuOK	1	<i>t</i> BuOH	rt	6	sm
B	<i>t</i> BuOK	2	<i>t</i> BuOH	rt	6	sm
C	<i>t</i> BuOK	5	<i>t</i> BuOH	rt	6	sm
D	<i>t</i> BuOK	1	<i>t</i> BuOH	60	6	0

Table 2.6.2: Conditions for alkylation of dienone **26** with methyl acrylate

We decided to pursue an alkylation with allyl bromide. Since the Nicolaou group already had success with allyl bromide as an alkylating agent, we saw this as a viable option. Although this would provide an earlier intermediate in the Nicolaou synthesis than originally planned, successful execution would still provide a short and concise formal synthesis.

Following the previous rationale, dienone **26** was alkylated with allyl bromide to give α -allyl dienone **60** in 67% yield (**Scheme 2.6.4**). The second alkylation with MeI was attempted but without success. The reaction was monitored *via* TLC and quenched upon consumption of the starting material. Following purification only dienone **26** was recovered. Initially this was a bit confusing. The reaction was repeated additional times, taking greater care in the way the product was isolated but continued to give similar

Scheme 2.6.4: Alkylation and subsequent alkylation of dienone **26**

results. We postulated that a competition between *O* and *C*-alkylation was occurring, with *O*-alkylation dominating the reaction. We proceeded to reverse the sequence of alkylation believing that if *O*-alkylation was indeed impeding the formation of the quaternary center we could force a Claisen rearrangement to give us the desired product (**Scheme 2.6.5**).

Scheme 2.6.5: Proposed Claisen rearrangement

On a side note, the alkylation of dienone **26** with methyl acrylate was revisited. This was in response to work published by the Corey group of a platensimycin analog.¹⁶ They reported the alkylation of enone **63** with methyl acrylate in good yield (**Scheme 2.6.6**). However, when this alkylation was attempted using their method none of the

desired product was obtained. Minor modifications were made to the procedure but all attempts failed to show any promise. This idea was quickly abandoned.

Scheme 2.6.6: Corey's alkylation with Methyl Acrylate

Subjecting α -methyl dienone **58** to deconjugative alkylating conditions gave epimers **61** and **65** in a 1:3 ratio (**Scheme 2.6.7**). Structures of enones **61** and **65** were assigned by IR and NMR. Their relative stereochemistries were later assigned through crystallographic data. It was determined that the minor product, enone **61**, was that of the desired stereochemistry (**Figure 2.6.1**). We were surprised to obtain two different compounds, since we expected to have a bias toward the desired stereochemistry. This notion stems from the Nicolaou synthesis, where they observed complete stereoselectivity in their sequence of alkylations (**Scheme 1.3.1**). We had assumed that the structure of dienone **26** was comparable to the structure of enone **10** that we would observe the same selectivity, unfortunately this was not the case.

Scheme 2.6.7: Enones **61 and **65****

Figure 2.6.1: Crystal Structure of enone **61**

Upon closer examination of the structure, published literature and molecular models we realized that the critical difference between our intermediate and those published was the hybridization of the β -carbon (**Figure 2.6.2**). In the structure of enone **61** and **65** the β -carbon is sp^2 hybridized and in the Nicolaou synthesis it is sp^3 hybridized. This change of hybridization has a major influence on the stereochemistry at the α -carbon due to the differences in conformation because of the γ -carbon (**Figure 2.6.2**).

Figures 2.6.2: Steric effects caused by difference in hybridization

The top face of Nicolaou's intermediate **10** is unavailable to electrophiles due to the steric congestion from the axial methylene groups (bold bonds) (**Figure 2.6.2**). This conformation gives complete stereoselectivity in forming the α -quaternary center. As can be seen from the crystal structure, the β -carbon of enone **61** is trigonal planar, forcing the bond between the β - and γ -gamma carbons (highlighted green) to be skewed down. This geometric restriction forces the δ -methylene (highlighted orange) to be moved away from the top face, exposing the top of the molecule to electrophiles. It is this difference in hybridization that has reversed the stereoselectivity of this alkylation.

2.7 Conclusion

We were successful in obtaining dienone **25** in gram quantities and in one step less than the Mulzer synthesis. Furthermore, we were able to improve the Grignard addition giving us an actual yield as opposed to a "brsm" yield. When we were unsuccessful in using methyl acrylate to install the α -quaternary center, we opted to use allyl bromide. Although success was met in forming the α -quaternary center using allyl bromide, the resulting mixture of enones favored undesired epimer **65** in a 3:1 ratio. We were able to surmise that the hybridization at the β -carbon had enough influence to affect the stereochemical outcome of this alkylation. These results compelled us to conceive a different strategy.

Chapter 3: Second Generation Synthesis

3.1 Introduction

As we have not yet achieved the desired stereoselectivity, we went on to devise a new strategy that would enforce the desired selectivity. From the Nicolaou synthesis and close examination of our work we knew it was crucial to form the ether linkage prior to alkylation. Consequently, our second generation strategy would revolve around this idea.

3.2 Synthetic Approach

Our new strategy started with dienone **26**. Dienone **26** would be converted to extended enol ether **66**. Epoxidation of enol ether **66** would give epoxide **67**. Hydrolysis of enol ether **67** would afford γ -hydroxy dienone **68**.^{1,2,3} A hydroxyl-directed reduction of dienone **68** to enone **69** followed by cyclization would give final product **10**. Enone **10** was chosen as our new goal because the succeeding alkylation had already been successfully accomplished by the Nicolaou group.

Scheme 3.2.1: Route to cyclic ether **10**.

3.3 Formation of the Extended Enol Ether

Initial attempts to make extended enol ether **66** using acetic anhydride failed to give any of the desired products (**Scheme 3.3.1**). This transformation was then attempted using TBDMS to form silyl enol ether **71**. TBDMS was used because we assumed that a TMS group would be too labile, as can be evidenced by how readily the methyl enol ether postulated to form in the alkylation of compound **59**, hydrolyzed. Dienone **26** was treated under standard silyl enol ether forming conditions but gave mostly recovered starting material and a minor product (~5%). After purification it was determined that the minor product was γ -hydroxy dienone **68**.

Scheme 3.3.1: Formation of the extended enol ether **66**.

The direct formation of γ -hydroxy dienone **68** from dienone **26** was a fortuitous result because it shortened our intended route by two steps (**Scheme 3.3.2**). Our efforts were now directed toward understanding and improving this transformation.

Scheme 3.3.2: Modified Synthetic Scheme.

3.4 Autoxidation

The origin of γ -hydroxy dienone **68** was uncertain so we explored this transformation by repeating the previous experiments. The results were poor with yields of **68** ranging from 4-7 %, with no signs of the desired enol ether. During these trials it was concluded that the process responsible for the oxidation at the γ -position was autoxidation ($^3\text{O}_2$). Furthermore, a result from a concurrent literature search gave further support to the notion that this reaction was occurring *via* an autoxidation process. Aladro and coworkers treated bicyclic enone **72** under autoxidation conditions to obtain γ -hydroxy enone **73** in 100% yield (**Scheme 3.4.1**).⁴

Scheme 3.4.1: Aldaro autoxidation.

The investigation proceeded with taking enone **26** and treating under the same conditions used by Aladro (**Table 3.4.1**). The reactions were left open to atmosphere unless otherwise noted. Under these conditions only a 10% yield was obtained (Entry A). No improvement was observed when the temperature or reaction

Scheme 3.4.2: Autoxidation of dienone **26**.

G*	KOH	MeOH	rt	48	10

*The reaction was run under an atmosphere of oxygen

Table 3.4.1: Autoxidation conditions for dienone **26**

time were increased. (Entry B,C). Changing to a stronger base or changing the solvent also failed to produce any positive results (Entry D-F). The use of an oxygen balloon had no impact on the yield (Entry G).

Having little success using dienone **26**, α -methyl dienone **58** was used instead. This was done in order to mirror more closely what the Diaz group published (**Scheme 3.4.2**). By simply substituting dienone **26** with α -methyl dienone **58**, γ -hydroxy compound **74** was obtained in 27% yield, almost a 3-fold increase in yield (**Table 3.4.2**, Entry A). Further changes to the procedure were fruitless. Prolonging the reaction from 48 h to 96 h had little effect (Entry B,C). Changing the base or the solvent caused a slight drop in yield (Entry D-F).^{5,6} The use of an oxygen balloon had little impact on the yield (Entry G).

G*	KOH	MeOH	rt	48 h	24

*the reaction was run under an atmosphere of oxygen

Table 3.4.2: Autoxidation conditions for α -methyl dienone **58**

Three new pieces of information were obtained from this reaction. First, due to the increase in yield, enough of the product was collected to obtain an x-ray structure of γ -hydroxy dienone **74** and the relative stereochemistry was assigned (**Figure 3.4.1**). The image displayed is a view from the bottom of the molecule to help show the *syn*-relationship of the hydroxyl groups. The γ -hydroxyl group was of the desired stereochemistry, perfectly situated for the envisioned hydroxyl-directed reduction. Furthermore, the γ -hydroxyl group was in proximity for the final transformation which was imagined to proceed under an acid catalyzed etherification *via* the tertiary carbocation.

Figure 3.4.1: Crystal structure γ -hydroxy dienone **74**

It was discovered that a major reason for the low yield of dienone **74** was the formation of ketone **76** which was isolated in 16-19% yield (**Figure 3.4.2**). Ketone **76** was thought to arise from the over oxidation of dienone **74**. It was postulated that when the peroxide formed at the γ -position, excess base deprotonated the remaining γ -proton to give ketone **76**. Since it accounted for such a significant percentage of the products isolated, it was imperative that we find a solution. Our initial thought was that using reducing agent might help deter this pathway by cleaving the oxygen-oxygen bond of the

Figure 3.4.2: Formation of ketone **73**

the peroxide before deprotonation occurred.

A commonly utilized reducing agent in autoxidation is $\text{P}(\text{OEt})_3$.⁷ The previous set of trials were repeated in the presence $\text{P}(\text{OEt})_3$ (**Scheme 3.4.3**). Overall the addition of $\text{P}(\text{OEt})_3$ caused a drop in the yield of ketone **76**. Additionally, the reaction time was significantly reduced. However, there was little improvement in the yield of the desired compound. The one reaction that caught our attention was the use of $t\text{BuOK}$ in THF (Entry E). This set of conditions produced the lowest yield of ketone **76**, while still providing a comparable yield of the desired product. The reason for this was not well understood but we shifted our attention to using $t\text{BuOK}$ instead of KOH .

Scheme 3.4.3: Auto-oxidation in the presence of $\text{P}(\text{OEt})_3$.

Entry	Base	Solvent	Temp (°C)	Time (h)	Yield (%) 74	Yield (%) 76
A	KOH	MeOH	rt	2.5	26	8
B	KOH	MeOH	60	2.5	0	0
C	$t\text{BuOK}$	MeOH	rt	2.5	20	7
D	KOH	THF	rt	2.5	21	8
E	$t\text{BuOK}$	THF	rt	2.5	23	4

Figure 3.4.3: Conditions for the autoxidation with $\text{P}(\text{OEt})_3$.

Increasing the amount of $\text{P}(\text{OEt})_3$ which had little impact on the yield (**Table 3.4.4**, Entry A-C). Raising or lowering the reaction temperature didn't provide any significant improvement (Entry D,E). Changing the solvent to $t\text{BuOH}$ had paralleled the

Entry	Base (2.5 eq)	P(OEt) ₃ (eq)	Solvent	Temp (°C)	Time (h)	Yield(%) 74	Yield(%) 76	Yield(%) 77

Table 3.4.4: Autoxidation of **58** using ^tBuOK.

results when THF was used (Entry F). This new development sparked interest into using ^tBuOH as a solvent. Realizing that when the temperature was increased loss of starting material was observed we decided to experiment with lower temperatures. THF had to be used as a co-solvent to prevent solidification of ^tBuOH at lower temperatures. Decreasing the temperature lowered the yield slightly but gave rise to a new side product (Entry G-I). It was determined that this side product was α -hydroxy enone **77** (Scheme 3.4.4). It was not too surprising since similar conditions have been employed to produce α -hydroxy ketones.⁸ Enone **77** helped us to conceive a possible mechanism for the autoxidation of α -methyl dienone **58** which will be later examined in detail. When the reaction was performed at room temperature with in THF/^tBuOH (1:1) mixture a slight increase in yield was observed (Entry J). Finally, when the amount of P(OEt)₃ was

Scheme 3.4.4: Products formed from the autoxidation of **58**.

increased a 30% yield was obtained with a minimal amount of ketone. These were the optimal conditions obtained thus far. Changing the amount of base, reductant, ratio of solvents or reaction time failed to improve these results. It is also important to mention that other reductants were used (PBU_3 , PPh_3) but provided inferior results.

Obtaining α -hydroxy enone **77** and studying molecular models allowed us to suggest a mechanism for the autoxidation and help understand its stereoselectivity (**Figure 3.4.3**). The reaction begins with deprotonation at the γ -position forming the extended enolate. Single electron transfer then occurs from the negatively charged oxygen to triplet oxygen. Homolytic cleavage of the α double bond leads to the formation of the carbonyl and α -peroxy bonds. It is at this step that the peroxide can either do an 2,3 sigmatropic rearrangement or be reduced to give α -hydroxy ketone **77**.⁹ Molecular models helped us understand that proper orbital overlap for the 2,3-sigmatropic rearrangement can only be achieved when the peroxide is on the bottom face of the molecule. After the 2,3 sigmatropic shift the peroxide can either be cleaved by P(OEt)_3 to give γ -hydroxy dienone **74** (red arrows) or the remaining γ -proton can be abstracted by $t\text{BuOK}$ leading to ketone **76** (blue arrows).

Figure 3.4.3: Autoxidation mechanism.

Although we had improved our yield to a consistent 30% and greatly reduced the amount of ketone **76**, it was still at best a modest yield. Furthermore the best results were obtained when the reaction was run on a small scale (30 mg). Running the reaction on

larger scales dropped the yield significantly. For these reasons we sought out alternatives in forming the γ -hydroxy dienone **74**.

We started by attempting an allylic oxidation with SeO₂ (**Table 3.4.5**, Entry A). At lower temperatures there was no visible change but when the temperature was raised only degradation of the starting material was observed. Similar results were obtained for all the other trials as well. When a source of electrophilic oxygen was used degradation of the starting material occurred (Entry B).¹⁰ Allylic acetate formation resulted in complex mixtures (Entry C-E).¹¹ It was thought that successful formation of the allylic acetate could yield γ -hydroxy dienone **74** *via* hydrolysis.

Entry	Conditions	Yield (%)
A	SeO ₂ , Dioxane, rt to reflux	0
B	^t BuOK, ^t BuOOH, Et ₃ N, ^t BuOH	0
C	Pd(OAc) ₂ , Benzoquinone, AcOH, rt, 6 h	0
D	Pb(OAc) ₄ , AcOH, 60 °C, 4 h	0
E	Hippuric Acid, NaOAc, AcOH, rt to reflux	0

Table 3.4.5: Alternative allylic oxidation methods.

During this time we made another discovery in the literature. The Yoshioka group had published a paper on the functionalization of the Wieland-Miescher ketone at the γ -position.¹² By using water as a co-solvent they completely eliminated the presence of ketone **80** (**Scheme 3.4.5**). Running the reaction under different conditions had

produced a substantial amount of ketone **80**. These conditions were applied to the autoxidation of dienone **58**.

Scheme 3.4.5: Yoshioka's Autoxidation.

Running the reaction under the same conditions yielded a small amount of product but without yielding any of the undesired ketone **76** (Table 3.4.6, Entry A). When the temperature was increased or the base changed from KOH to ^tBuOK no significant improvement was made (Entry B,E,F). However, when ^tBuOH was used as a co-solvent a significant improvement in yield was observed (Entry C). Increasing the reaction temperature lead to a reduction in yield by about 50% (Entry D). Unexpectedly, the mixture of base with a ^tBuOH/H₂O formed a biphasic system. This observation lead us to explore the use of phase transfer catalysts (PTCs).

Entry	Base (10%)	Solvent	Time (days)	Temp (°C)	Yield(%) 74	Yield(%) 76
A	KOH	MeOH/ H ₂ O(1:1)	5	rt	7	0

F	tBuOK	^t BuOH/ H ₂ O (1:1)	5	65	4	0

Table 3.4.6: Autoxidation using Yoshioka conditions.

By screening various PTCs at 10 mol % it was determined that Bu₄NBr showed the most promise in improving the yield so further experiments were performed using only Bu₄NBr (**Table 3.4.7**). The first trial showed improvement in yield and a reduction in reaction time by 2 days (Entry A). Increasing the amount of PTC had a slight increase in yield but more importantly decreased the reaction time to 2 days (Entry B-F). Changing the solvent, base, or temperature provided inferior results. Furthermore, this reaction was performed on a 100 mg scale, 3 times greater than previous scale.

Entry	Base (10%)	Solvent	PTC %	Time (days)	Temp	Yield (%)
A	KOH	^t BuOH/H ₂ O(1:1)	10	3	rt	60

F	KOH	^t BuOH/H ₂ O(1:1)	100	2	rt	65

Table 3.4.7: Autoxidation using aBu₄NBr.

Through these experiments the optimal conditions for producing γ -hydroxy dienone **74** in 65% yield were obtained (**Scheme 3.4.6**). Moreover, it was discovered that the use of water as a co-solvent helped to deter over oxidation to unwanted ketone **76**. We were able to gain a working hypothesis as to the mechanism that was operating in the autoxidation. Finally, the crystal structure was solved and showed that we had obtained the desired relative stereochemistry (**Figure 3.4.1**)

Scheme 3.4.6: Optimal autoxidation conditions.

3.5 Hydroxyl-Directed Conjugate Reduction

Having been able to unambiguously assign the stereochemistry of the γ -hydroxyl group put us in good position to attempt the desired hydroxyl directed conjugate reduction. At the onset we had two ideas on how to achieve this objective. The first was a reduction based on an intramolecular hydrosilylation and the second a reduction based on LAH.

We started by silylating γ -hydroxy dienone **74** to give compound **81** (**Scheme 3.5.1**). This compound was then treated to a variety of conditions to affect the conjugate reduction (**Tabel 3.5.1**). Treating compound **81** to Wilkinson's catalyst resulted in degradation of the reactant (Entry A).¹³ The use of Lewis acids resulted in desilylation (entry B,C).^{14,15} Using I_2O_5 resulted in the degradation of the starting material.¹⁶ Having shown little promise we shifted our attention to an LAH reduction.

Scheme 3.5.1: Formation of silyloxy compound **81**.

Entry	Conditions	Yield (%)
A	(Ph ₃ P) ₃ RhCl, THF, 6 h, rt - reflux	0
B	SnCl ₄ , DCM, -78° C, 3 h	0
C	TiCl ₄ , DCM, - 78 °C 3 h	0
D	I ₂ O ₅ , rt, DCM, 5 h	0

Table 3.5.1: Conditions for the intramolecular hydrosylation.

The idea for the LAH reduction stemmed from work published by the Liotta group (**Scheme 3.5.2**).¹⁷ They treated dieone **82** with LAH and obtained diastereomer **83** in 90% yield. These conditions were taken and applied to γ -hydroxy dienone **74** (**Table 3.5.2**). All the reactions were done in THF with LAH (1eq). When the reaction was done at ambient temperature a distribution of three compounds were isolated, enone **84**, **85**, and dieneone **74** (Entry A). As the temperature was decreased a greater amount of enones **84** and **85** were isolated (Entry A,C,E). When the reaction continued until complete consumption of dienone **74**, low yields and poor mass balance were observed (Entry B,D,F). The best results were obtained when there reaction was performed at -78 °C for one minute (Entry E). The same experiments were performed with the addition CuI/HMPA, which have been shown to aid LAH in conjugate reductions, but offered no advantage over the previous examples.^{18,19,20}

Scheme 3.5.2: Liotta's conjugate reduction of dienone **82**.

Scheme 3.5.3: Conjugate reduction using LAH.

Entry	Temp (°C)	Time (min)	Yield (%) 84	Yield (%) 85	Yield (%) 74

B	t	5	4	19	0
C	0	1	15	24	30
D	0	12	11	23	0
E	-78	1	32	32	34
F	-78	45	14	26	0

Table 3.5.2: Conditions for LAH reduction.

The next improvement came upon an observation using a new bottle of LAH. When the reduction was performed under the current conditions only a small amount of the products were obtained (~10% combined) with a poor mass balance. It had then occurred to us that the bottle that we had been using was a bit older and postulated that

moisture may have entered the original bottle thereby forming $\text{LAH}_x(\text{OH})_y$ adducts. These adducts would stand to be less reactive than pure LAH.

Previous studies had been done on the reactivity of LAH reagents modified with alkoxy groups by the Brown and Ashby Groups.^{21,22} The general trend they observed for reactivity of these adducts was $\text{OH} \geq \text{MeOH} > \text{EtOH} > \text{iPrOH} \gg \text{tBuOH}$. The number of alkoxy groups on the LAH moiety also affected its reactivity, with the greater number of displaced hydrides the more reactivity decreased. Based on previous results we decided to start the next set of experiments with a $\text{LAH}_x(\text{EtO})_y$ adducts (**Table 3.5.3**). When only one hydride was displaced and the reaction run at -78°C a bias toward the desired product was observed (Entry A). When the reactivity was decreased by adding a second ethoxy group complete selectivity was obtained (Entry B). Adding an additional ethoxy

Entry	Adduct	Temp ($^\circ\text{C}$)	Time (min)	Yield(%) 84	Yield(%) 85	Yield(%) 74
A	LiAlH_3OEt	-78	15	40`	19	35

E	$\text{LiAlH}_2(\text{OEt})_2$	0	15	45	15	35
F	$\text{LiAlH}_2(\text{OEt})_2$	rt	5	5	30	10

Table 3.5.3: Conjugate reduction with LAH-ethoxy adducts.

failed to provide any new results as was expected with only one available hydride. As the temperature was raised yields decreased and the desired selectivity was lost (Entry C-F). The use of isopropoxy or tertbutoxy groups failed to provide any of the reduced products at low temperatures. When the reactions were run at high temperatures using

these reagents (+60 °C) the starting material was consumed and inextricable mixtures were obtained.

The end result was a 65% yield of enone **84** when γ -hydroxy dienone **74** was treated to $\text{LiAlH}_2\text{OEt}_2$ at $-78\text{ }^\circ\text{C}$ (**Scheme 3.5.4**). The crystal structure was obtained and the relative stereochemistry assigned (**Figure 3.5.1**). It is clear that the hydrogen on the β -carbon was delivered from the bottom face, signaling that this was indeed a hydroxyl directed reduction. The major drawback of this reaction is the purification. It was very difficult to separate the starting material from the products. As such, the subsequent transformation was undertaken with a mixture of dienone **74** and **84**. It is worthy of note that other reducing reagents/methods failed to give any positive results (Alane, Borane, DIBAL-H, and Birch).

Scheme 3.5.4: Hydroxy directed conjugate reduction.

Figure 3.5.1: Crystal structure of enone **84**.

3.6 Cyclization

The final step of our synthesis was the cyclization of enone **84**. It was initially envisioned that this transformation could be achieved *via* acid catalysis. This method was employed by Nicolaou in the etherification of compound **9** (Scheme 3.6.1). These

Scheme 3.6.1: Nicolaou's acid induced cyclization

conditions were taken and applied to substrate **74** (Scheme 3.6.2). The results were discouraging and surprising (Table 3.6.1). At best only 6% of the desired product was obtained, along with *epi*-compound **87** and cyclized dienone **88** (Entry A). Using stronger acids lead solely to the cyclized dienone (Entry B,C,E).²³ When weaker acids

were employed only the yield of cyclized dienone increased. (Entry D). The formation of *epi*-compound **87** was not surprising, since it is known that tetrahydrofurans are readily cleaved under acidic conditions. What was surprising was other sources reported this transformation in moderate to good yields (57-87%) without any epimerization.

Scheme 3.6.2: Formation of cyclic ether **86**.

Entry	Acid	Solvent	Time (h)	Temp (°C)	Yield(%) 86	Yield(%) 87	Yield(%) 88
A	TFA	DCM	2	0	6	3	56
B	TfOH	DCM	1.5	-78	0	0	23
C	HCl	Dioxane	2	0	0	0	28
D	AcOH	neat	24	40	0	0	67
E	Nafion	DCE	12	rt	0	0	60

Table 3.6.1: Acid catalyzed conditions for the ether formation.

Short of any promising results we looked to inverting the stereochemistry of the secondary alcohol and perform an intramolecular $\text{S}_{\text{N}}2$ displacement. This displacement would be done under basic conditions, thus avoiding the opening of the furan ring. We began by exploring Mitsunobu chemistry (**Table 3.6.2**). When standard or modified conditions were employed the starting material was destroyed (Entries A, B).²⁴ It has been shown that Cyanomethylene/triethylphosphorane (CMMP/ Tsunoda's Reagent), a modified Mitsunobu reagent, could enact an inversion and intramolecular cyclization in one pot.^{25,26} When CMMP was used only degradation products were isolated (Entry C). Foregoing Mitsunobu chemistry, Appel chemistry was attempted but that failed to give the desired bromide (Entry D). The use of P_2I_4 resulted in degradation of starting material (Entry E).²⁷ Attempting to form the bromide by displacing the mesylate also failed to give any new results (Entry F).

Scheme 3.6.3: Inversion of the secondary alcohol.

Entry	Conditions	Yield (%)
A	standard Mitsunobu	0
B	DEAD, Ph_3P , $\text{Zn}(\text{OTs})_2$, THF, 3 hr	0
C	CMMP, THF, 65 °C, sealed tube	0
D	Ph_3P , CBr_4 , DCM, rt	0
E	P_2I_4 , THF, 0 °C, 5 h	0
F	MsCl , NEt_3 , DCM, rt then LiBr	0

Table 3.6.2: Conditions for the inversion of the secondary alcohol.

Lacking any positive results from the previous experiments we looked at forming the cyclic ether by forming a carbonate moiety with the two hydroxyl groups. With this compound we envisioned enforcing an intramolecular cyclization to produce compound **11**. Initial attempts with thionyl chloride, phosgene and methyl carbonate all provided inextricable mixtures. However, when DMSO was utilized we were able to affect the desired transformation in 65% yield (**Scheme 3.5.5**).²⁸

Scheme 3.6.5: Cyclization using DMSO.

We postulate that the ether formation is occurring *via* the tertiary carbocation. Ionization of the hydroxyl group followed by ring closure from the secondary alcohol gives compound **11** (Figure 3.6.1). We believe we were able to achieve this etherification due to the relatively neutral reaction conditions, whereas when acidic conditions were employed only degradation and inversion products were isolated.

Figure 3.6.1 Mechanism for the ether formation.

3.7 Conclusion

We were able to achieve a concise, direct and stereoselective formal synthesis of platensimycin. This was accomplished in 11 linear steps starting from commercially available 6-methoxy-1-tetralone in a 5% overall yield. To date this is the shortest route to α -methyl enone **11**.

Our original plan did not materialize for two reasons. The first, a minor impediment, was the inability to successfully install the α -quaternary center using methyl acrylate. This was circumvented with the use of allyl bromide in a Claisen rearrangement. However, the issue of stereoselectivity was irreparable and forced us to re-work our strategy.

The second generation synthesis centered on forming the ether linkage prior to alkylation to affect the desired stereoselectivity. This route was almost immediately

improved due to serendipitous results. The autoxidation of α -methyl dienone **58** proved to be a useful intermediate, shortening the planned synthetic route by 2 steps. Furthermore, we achieved the desired stereochemistry at all the newly formed stereocenters. Finally, we were able to form the ether linkage in relatively neutral conditions to complete the formal synthesis of platensimycin.

Chapter 4: Experimental Section

4.1 General Information

All moisture sensitive reactions were performed under an atmosphere of dry Ar, with glassware pre-dried at 125 °C. THF was dried via distillation over Na/benzophenone and ^tBuOH by distillation over Na(m). All other reagents or solvents were used as received, without further purification, unless otherwise stated. Infrared spectra were recorded on a Nicolet FT-IR spectrophotometer in methylene chloride. ¹H and ¹³C NMR spectra were recorded on a QE 300, Varian Unity+ 300 spectrometer at 300 or 600 MHz and 75 or 150 MHz, respectively, and are reported in ppm relative to tetramethylsilane. All NMR spectra were taken with CDCl₃ as solvent unless otherwise noted. Mass spectra were obtained on a VG ZAB2E or a Finnigan TSQ70. Column chromatographic separations were carried out on silica gel (SilicaGel 60, 230-400 mesh) under pressure.

4.2 Experimental Conditions and Compound Data

54

α - β Keto ester (54). Sodium hydride (60% suspension in mineral oil, 3.4g, 85 mmol) was added to methyl carbonate (71.0 mL, 740 mmol) under argon. After about 0.5 h tetralone **22** (10.0 g, 56.8 mmol) was added to this suspension. The reaction mixture was heated to about 80 °C for about 5 h. The reaction mixture was allowed to cool to ambient temperature and acidified with an aqueous solution of HCl (2M). The aqueous layer was then extracted with EtOAc (3 x 50 mL). The organic layers were combined, washed with a saturated aqueous solution of NaHCO₃ and brine, and dried over Na₂SO₄. The solvent was removed under reduced pressure to afford dark brown solid (13.3 g, 56.8 mmol). The crude mixture was carried on to the next step. IR (thin film) 2950, 1740, 1676, 1600 cm⁻¹; ¹H NMR (300 MHz, CDCl₃): δ 8.03 (1H, d, J = 6.9 Hz), 6.85 (1H, dd, J = 6.9, 1.8 Hz), 6.70 (1H, d, J = 1.8), 3.87 (3H, s), 3.79 (3H, s), 3.61-3.57 (1H, m), 3.04-2.96 (2H, m), 2.51-2.31 (2H, m); ¹³C NMR (75 MHz, CDCl₃): δ 192.0, 171.1, 164.2, 146.4, 130.5, 125.5, 113.7, 112.8, 55.7, 54.4, 52.6, 28.2, 26.7; HRMS calcd. for C₁₃H₁₅O₄ [MH⁺]: 235.097; found: 235.096

24

Carboxylic Acid 24. A crude mixture of **54** (56.8 mmol, crude), AcOH (140 mL), 10% Pd/C (3.00 g, 2.83 mmol) and 70% HClO₄ (5.0 mL, 83 mmol) was subjected to pressurized hydrogen gas (45 psi) for about 5 h. After about 5 h NaOAc (3.5 g, 43 mmol) was added and stirred for about 15 min. The resulting mixture was filtered over celite, and the filtrate was concentrated *in vacuo* to produce a light brown oil. The crude mixture was dissolved in MeOH (75 mL). To this was added a solution of KOH (7.0 g, 125 mmol), dissolved in H₂O (75 mL), and maintained at ambient temperature for about 7 h. The MeOH was removed under reduced pressure, and the resulting aqueous layer was washed with Et₂O (2 x 50 mL). The aqueous layer was then acidified with an aqueous solution of HCl (2M) and extracted with EtOAc (3 x 50 mL). The organic extracts were combined, washed with water and brine, and dried over Na₂SO₄. The solvent was then removed under reduced pressure to afford white solid **24** (9.8 g, 84% yield over two steps). IR (thin film) 2935, 2838, 1688, 1609 cm⁻¹; ¹H NMR (300 MHz, CDCl₃): δ 7.05 (1H, d, *J* = 8.4 Hz), 6.73 (1H, d, *J* = 8.4 Hz), 6.66 (1H, br s), 3.80 (3H, s), 3.07-2.77 (5H, m), 2.28-2.24 (1H, m), 1.99-1.87 (1H, m); ¹³C NMR (75 MHz, CDCl₃): δ 182.1, 158.0, 136.9, 130.2, 126.9, 113.6, 112.5, 55.5, 40.3, 30.9, 28.9, 25.8; 176.6, 156.7, 136.1, 129.0, 126.4, 112.5, 111.3, 54.3, 39.1, 30.0, 27.9, 24.9; HRMS calcd for C₁₂H₁₅O₃ [MH⁺]: 207.1021; found: 207.1023.

57

Diazoketone 57. Carboxylic acid **24** (4.00 g, 19.3 mmol) was dissolved in SOCl_2 (21 mL, 289 mmol) and stirred under argon for about 5 h at ambient temperature. The thionyl chloride was removed under reduced pressure, and the resulting mixture was concentrated under vacuum (5mm). The residue was dissolved in Et_2O (20 mL) and added to a freshly prepared solution of diazomethane (3.42 g, 81.5 mmol) in Et_2O (150 mL) at about 0°C . The reaction was maintained at about 0°C for about 30 min. The reaction mixture was allowed to warm to ambient temperature and then gently refluxed for about 1 h. The solvent was then removed under reduced pressure to produce diazoketone **57** as a yellow solid (4.73 g, 19.3 mmol). The diazoketone was immediately carried on to the next reaction. IR (thin film) 3092, 2932, 2837, 2103, 1636 cm^{-1} ; ^1H NMR (300 MHz, CDCl_3): δ 7.02 (1H, d, $J = 8.4$ Hz), 6.72 (1H, dd, $J = 8.3, 2.7$ Hz), 6.65 (1H, d, $J = 2.4$ Hz), 5.38 (1H, bs), 3.80 (3H, s), 2.93-2.83 (4H, m), 2.65 (1H, bs), 2.09–2.07 (1H, m), 1.87–1.85 (1H, m); ^{13}C NMR (75 MHz, CDCl_3): δ 197.7, 158.0, 137.0, 130.2, 127.2, 113.7, 112.5, 55.5, 54.1, 46.2, 31.3, 29.2, 26.3; HRMS calcd for $\text{C}_{13}\text{H}_{15}\text{N}_2\text{O}_2[\text{MH}^+]$: 231.1134; found: 231.1135

25

Dienone 25: Diazoketone **57** (4.73 g, 19.3 mmol, crude) was dissolved in DCM (20 mL) and cooled to about -10 °C. TFA (10 mL) was then added slowly and the reaction was maintained at about -10 °C for about 30 min. The reaction mixture was diluted with water (10 mL), removed from the cold bath, and neutralized with a saturated aqueous solution of NaHCO₃. The aqueous layer was extracted with DCM (3 x 30 mL). The organic extracts were then combined, washed with water and brine, and dried over Na₂SO₄. The mixture was filtered and the solvent was removed *in vacuo*. The crude product was purified by silica column chromatography (solvent gradient from 5/95 EtOAc/Hex to 60/40 EtOAc/Hex) to produce dienone **25** as a yellow solid (2.19 g, 60% yield over three steps). IR (thin film) 2953, 1745, 1661, 1624 cm⁻¹; ¹H NMR (300 MHz, CDCl₃): δ 6.75 (1H, d, *J* = 9.6 Hz), 6.19 (1H, dd, *J* = 9.6, 1.8 Hz), 5.98 (1H, d, *J* = 1.8 Hz), 2.61-2.11 (6H, m), 1.98-1.90 (1H, m), 1.66-1.60 (2H, m); ¹³C NMR (75 MHz, CDCl₃): δ 216.3, 186.5, 163.0, 152.1, 129.0, 124.2, 48.8, 46.6, 46.3, 42.1, 29.3, 28.7; HRMS calcd. for C₁₂H₁₃O₂ [MH⁺]: 189.0915; found: 189.0913.

26

Tertiary alcohol 26. Dienone **25** (5.0 g, 27 mmol) was dissolved in anhydrous THF (78 mL) under argon and cooled to about -78 °C. To the solution was added 3.0 M MeMgCl in THF (27 mL, 80 mmol), and the reaction was maintained at about -78 °C for about 4 h. The reaction was removed from the cold bath, quenched with water (20 mL), and neutralized with a saturated aqueous solution of NH₄Cl. The aqueous layer was then extracted with EtOAc (3 x 50 mL). The organic layers were combined, washed with brine and dried over Na₂SO₄. The organic layer was then filtered and removed under reduced pressure. The crude mixture was purified through silica column chromatography (solvent gradient from 5/95 EtOAc/DCM to 50/50 EtOAc/DCM). Tertiary alcohol **26** was obtained as a pale yellow solid (3.42 g, 63% yield). IR (thin film) 3403, 2955, 2936, 2860, 1654, 1615, 1599 cm⁻¹; ¹H NMR (300 MHz, CDCl₃): δ 6.68 (1H, d, *J* = 9.6 Hz), 6.22 (1H, d, *J* = 9.9 Hz), 6.03 (1H, s), 2.98-2.86 (1H, m), 2.43 (1H, dd, *J* = 15.9, 6.3 Hz), 2.28-2.17 (2H, m), 2.00 (1H, d, *J* = 14.4 Hz), 1.89 (1H, dd, *J* = 14.3, 2.4 Hz), 1.61-1.56 (1H, m), 1.55 (3H, s), 1.50 (1H, dd, *J* = 11.1, 2.1 Hz); ¹³C NMR (75 MHz, CDCl₃) δ 187.4, 169.3, 154.6, 129.0, 122.1, 80.0, 51.2, 49.3, 46.8, 44.7, 33.1, 30.3, 28.1; HRMS calcd. for C₁₃H₁₇O₂ [MH⁺]: 205.1229 found 205.1231.

58

α -Methyl dienone 58. Dienone **26** (3.00 g, 14.7 mmol) was dissolved in anhydrous t BuOH (48 mL) under argon. To the reaction mixture t BuOK (3.62 g, 32.3 mmol) was added and the resulting solution was stirred at ambient temperature for about 1 h. Freshly distilled MeI (0.91 mL, 14.7 mmol) was added and the reaction mixture was maintained at ambient temperature for about 1 h. The resulting mixture was quenched with water (15 mL) and then neutralized with an aqueous solution of HCl (1M). The aqueous layer was extracted with EtOAc (3 x 35 mL). The organic extracts were combined, washed with brine, and dried over Na_2SO_4 . The organic layer was then filtered and the solvent removed in *vacuo*. The crude mixture was purified by silica column chromatography (solvent gradient from 5/95 EtOAc/Hex to 40/60 EtOAc/Hex). Methyl dienone **58** was obtained as pale yellow solid (1.96 g, 61%). IR (thin film) 2953, 2924, 2852, 1653, 1616, 1599 cm^{-1} ; ^1H NMR (300 MHz, CDCl_3): δ 6.61 (1H, d, $J = 10.2$ Hz), 6.23 (1H, d, $J = 9.6$ Hz), 2.81 (1H, dd, $J = 16.2, 9$ Hz), 2.74-2.67 (1H, m), 2.27-2.06 (3H, m), 1.97 (1H, d, $J = 14.7$ Hz), 1.88 (3H, s), 1.84 (1H, dd, $J = 14.7, 3.0$ Hz), 1.67-1.54 (1H, m), 1.53 (3H, s), 1.48 (1H, dd, $J = 11.1, 2.4$ Hz); ^{13}C NMR (75 MHz, CDCl_3): δ 165.6, 160.6, 153.9, 127.8, 79.7, 51.4, 48.7, 46.3, 43.9, 32.7, 29.6, 27.3, 25.8, 10.4; HRMS calcd. for $\text{C}_{14}\text{H}_{19}\text{O}_2$ [MH^+]: 219.3148 found 219.3149.

60

α -Allyl dienone 60. Dienone **26** (200 mg, 0.98 mmol) was dissolved in anhydrous t BuOH (5 mL) under argon. To the reaction mixture t BuOK (242 mg, 2.16 mmol) was added, and the resulting solution was stirred at ambient temperature for about 1 h. Allyl bromide (0.09 mL, 0.98 mmol) was added, and the reaction mixture was maintained at ambient temperature for about 4 h. The reaction was quenched with water (5 mL) and neutralized with an aqueous solution of HCl (1M). The aqueous layer was extracted with EtOAc (3 x 15 mL). The organic extracts were combined, washed with brine, and dried over Na_2SO_4 . The organic layer was then filtered, and the solvent removed in *vacuo*. The crude mixture was purified by silica column chromatography (solvent gradient from 5/95 EtOAc/Hex to 60/40 EtOAc/Hex). Allyl dienone **60** was obtained as pale yellow solid (160.4 mg, 67%). IR (thin film) 3421, 2961, 2864, 1654, 1616, 1597 cm^{-1} ; ^1H NMR (300 MHz, CDCl_3): δ 6.63 (1H, d, J = 9.6 Hz), 6.23 (1H, d, J = 9.3 Hz), 5.84-5.75 (1H, m), 4.95 (1H, s), 4.95 - 4.89 (1H, m), 3.18-3.16 (2H, m), 2.75-2.68 (2H, m), 2.35 - 2.09 (3H, m), 1.97 (1H, d, J = 14.4), 1.90 (1H, dd, J = 14.4, 2.1 Hz), 1.53 (3H, s), 1.49 - 1.45 (2H, m); ^{13}C NMR (75 MHz, CDCl_3): δ 185.9, 163.0, 154.4, 135.0, 128.9, 128.2, 114.5, 80.1, 51.7, 49.2, 46.6, 44.6, 32.9, 28.7, 27.9, 26.1; HRMS calcd. for $\text{C}_{16}\text{H}_{21}\text{O}_2$ [MH^+]: 245.1545 found 245.1542.

Enones 61 and 65. Dienone **26** (459 mg, 2.11 mmol) was dissolved in anhydrous *t*BuOH (24 mL). To the reaction mixture *t*BuOK (1.71g, 6.31 mmol) was added, and the resulting solution was maintained at ambient temperature under argon for 1 h. The solution was treated with allyl bromide (0.36 mL, 4.21 mmol) and the resulting solution was refluxed in a sealed tube for about 1 h. The reaction was then quenched with water (15 mL) and neutralized with a saturated aqueous solution of NH₄Cl. The aqueous layer was then extracted with EtOAc (3 x 30 mL). The organic layers were combined, washed with brine, and dried over Na₂SO₄. The organic layer was filtered, and the solvent was removed under reduced pressure. The crude mixture was purified by silica column chromatography (1:3 EtOAc/Hex). Products **61** and **65** were obtained as white crystals in a 1:3 diastereomeric ratio (521 mg, 95% yield).

74

γ -Hydroxy dienone 74. A biphasic system was prepared by dissolving KOH (1 g, 17.8 mmol) in *t*BuOH (4.5 g) and water (4.5 mL). A portion of the aqueous layer (2 mL) and a portion of the organic layer (2 mL) were combined and treated with compound **58** (100 mg, 0.46 mmol) at ambient temperature. Following dissolution of **58**, the mixture was treated with N(n-Bu)₄Br (147.7 mg, 0.46 mmol) and maintained at ambient temperature, open to atmosphere, for about 2 days. The reaction mixture was then diluted with water (5 mL) and neutralized with an aqueous solution of HCl (1 M). The aqueous layer was extracted with EtOAc (3x10 mL). The organic layers were combined, washed with brine, and dried over Na₂SO₄. The crude mixture was filtered and the solvent removed under reduced pressure. After column chromatography (solvent gradient from 5/95 EtOAc/DCM to 40/60 EtOAc/DCM), hydroxyl dienone **74** was obtained as a white solid (69.8 mg, 65%). IR (thin film) 3293, 2965, 2928, 2868, 1656, 1618 cm⁻¹; ¹H NMR (300 MHz, CDCl₃): δ 6.65 (1H, d, *J* = 9.6 Hz), 6.24 (1H, d, *J* = 9.6 Hz), 5.17 (1H, br), 4.97 (1H, d, *J* = 6.0 Hz), 4.85 (1H, br), 2.42 (1H, d, *J* = 15.3 Hz), 2.22-2.17 (2H, m), 2.12-2.02 (2H, m), 1.96 (3H, s), 1.93-1.84 (3H, m), 1.49 (3H, s); ¹³C NMR (75 MHz, CDCl₃): δ 187.6, 157.4, 155.7, 131.5, 127.7, 79.2, 65.0, 50.9, 48.1, 46.6, 43.7, 35.1, 31.2, 10.7; HRMS calcd. for C₁₄H₁₉O₃ [MH⁺] 235.1334. Found 235.1334.

81

Silyloxy dienone 81. A solution of $i\text{Pr}_2\text{SiHCl}$ (0.09mL, 0.52mmol), DMAP (20mg, 17 mmol), Et_3N (0.072 mL, 17 mmol) dissolved in DCM (8 mL) was added a solution of γ -hydroxy dienone **74** (100 mg, 0.13 mmol) in DCM (6 mL) *via* syringe. The reaction was maintained at ambient temperature for about 12 h. The reaction was then diluted with water (15 mL) and extracted with DCM (3 x 15 mL). The organic layers were combined, washed with brine, and dried over Na_2SO_4 . The solvent was removed under reduced pressure and purified by column chromatography (5:95 EtOAc/Hex). The silyloxy dienone was obtained as a yellow solid (119 mg, 99%). IR (thin film) 3290, 2940, 2865, 2100, 1653, 1617 cm^{-1} ; ^1H NMR (300 MHz, CDCl_3): δ 6.62 (1H, d, $J = 9.9$ Hz), 6.27 (1H, d, $J = 9.9$ Hz), 4.99 (1H, d, $J = 6.0$ Hz), 4.23 (1H, s), 2.44 (1H, d, 15.3), 2.23-2.18 (2H, m), 2.14-2.03 (3H, m), 1.99 (3H, s), 1.95-1.87 (1H, m) 1.51 (3H, s) 1.11-0.98 (14H, m); ^{13}C NMR (75 MHz, CDCl_3): δ 187.5, 157.2, 155.4, 131.6, 127.8, 79.2, 65.2, 51.9, 48.0, 46.6, 43.6, 35.0, 31.3, 17.4, 12.9, 10.7; HRMS calcd. for $\text{C}_{20}\text{H}_{33}\text{O}_3\text{Si}$ $[\text{MH}^+]$ 349.2199. Found 349.2198.

84

Enone 84. Dienone **74** (50 mg, 0.21 mmol) was dissolved in THF (2.13 mL) and cooled to about -78°C under an atmosphere of argon. To the resulting solution was added $\text{LiAlH}_2(\text{OEt})_2$ (0.12 mL, 1.8 M, 0.21 mmol). After about 0.5 h the reaction was quenched with MeOH (5mL) and diluted with water (10 mL). The solution was neutralized with an aqueous solution of HCl (1M). The resulting solution was extracted with EtOAc (3x10 mL). The organic layers were combined, washed with brine, and dried over Na_2SO_4 . The solvent was removed *in vacuo* and to give pale yellow oil. The crude mixture was purified by column chromatography (5-50% EtOAc/DCM) to provide a mixture (2:1) of enone **84** and dienone **74** (48 mg, 64%) as a white solid. IR (thin film) 3280, 2964, 2927, 2874, 2855, 1670 cm^{-1} ; ^1H NMR (300 MHz, CDCl_3): δ 6.63 (1H, d, $J = 9.9$ Hz), 5.93 (1H, d, $J = 9.9$ Hz), 4.15 (1H, d, $J = 5.4$ Hz), 2.44 (1H, d, $J = 2.1$ Hz), 2.39-2.2.29 (3H, m), 2.11-2.03 (2H, m), 1.91-1.83 (2H, m), 1.73-1.63 (2H, m), 1.46 (3H, s), 1.31-1.18 (3H, m); ^{13}C (75 MHz, CDCl_3): δ 20.2, 158.8, 127.8, 78.9, 67.2, 55.9, 53.5, 45.9, 44.6, 41.4, 37.4, 32.7, 31.4, 13.5; HRMS calcd. for $\text{C}_{14}\text{H}_{21}\text{O}_3$ $[\text{MH}^+]$ 237.1491. Found 237.1491.

11

Cyclized enone 11. A mixture (2:1) of compounds **74** and **84** (50 mg, 0.13 mmol) was dissolved in DMSO (1 mL) and delivered to a microwave reaction vessel. The reaction was heated for about 1 h at 170 °C. The reaction was allowed to cool to ambient temperature, and water was added (3 mL). The resulting solution was extracted with Et₂O (3x10 mL). The organic layers were combined, washed with brine, and dried over Na₂SO₄. The solvent was removed under reduced pressure resulting in dark brown oil. The crude mixture was purified by column chromatography (solvent gradient from 0/100 EtOAc/hexanes to 30/70 EtOAc/hexanes) to give **11** (21 mg, 65%). IR (thin film) 2962, 2927, 2871, 1683 cm⁻¹; ¹H NMR (600 MHz, CDCl₃): δ 6.51(1H, d, *J* = 9.6 Hz), 5.90 (1H, d, *J* = 9.6 Hz), 4.33 (1H, t, *J* = 4.2 Hz), 2.37-2.30 (2H, m), 2.05 (1H, d, *J* = 13.8 Hz), 1.96-1.91 (1H, m), 1.92-1.88 (1H, m), 1.85 (1H, d, *J* = 11.4 Hz), 1.77 (1H, dd, *J* = 12, 3.6 Hz), 1.73-1.70 (1H, m), 1.6 (1H, d, *J* = 10.8), 1.42 (3H, s), 1.11 (3H, d, *J* = 6.6 Hz); ¹³C NMR (75 MHz, CDCl₃): δ 201.6, 154.4, 128.4, 87.1, 77.9, 52.1, 48.8, 46.8, 44.6, 42.8, 41.5, 37.4, 23.3, 11.2. HRMS calcd. for C₁₄H₁₉O₂ [MH⁺] 219.1385. Found 219.1384

Appendix A: X-Ray Data for Epimer 61

X-ray experimental for 61:

Crystals grew as colorless needles by slow evaporation of the mother liquor. The data crystal was a needle that had approximate dimensions; 0.38 x 0.09 x 0.06 mm. The data were collected on a Nonius Kappa CCD diffractometer using a graphite monochromator with MoK α radiation ($\lambda = 0.71073\text{\AA}$). A total of 348 frames of data were collected using ω -scans with a scan range of 0.8° and a counting time of 140 seconds per frame. The data were collected at 153 K using an Oxford Cryostream low temperature device. Details of crystal data, data collection and structure refinement are listed in Table 1. Data reduction were performed using DENZO-SMN.¹ The structure was solved by direct methods using SIR97² and refined by full-matrix least-squares on F^2 with anisotropic displacement parameters for the non-H atoms using SHELXL-97.³ The hydrogen atoms on carbon were calculated in ideal positions with isotropic displacement parameters set to 1.2xUeq of the attached atom (1.5xUeq for methyl hydrogen atoms). The hydrogen atoms bound to the hydroxyl oxygen atoms were observed in a ΔF map and refined with isotropic displacement parameters. The direction of the polar z axis could not be determined from the X-ray data and was arbitrarily assigned. The function, $\Sigma w(|F_o|^2 - |F_c|^2)^2$, was minimized, where $w = 1/[(\sigma(F_o))^2 + (0.0573*P)^2 + (0.8863*P)]$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. $R_w(F^2)$ refined to 0.147, with $R(F)$ equal to 0.0676 and a goodness of fit, S , = 1.06. Definitions used for calculating $R(F)$, $R_w(F^2)$ and the goodness of fit, S , are given below.⁴ The data were checked for secondary extinction effects but no correction was necessary. Neutral atom scattering factors and values used to calculate the linear absorption coefficient are from the International Tables for X-ray Crystallography (1992).⁵ All figures were generated using SHELXTL/PC.⁶

Table 4.1. Crystal data and structure refinement for **71**

Empirical formula	C17 H22 O2
Formula weight	258.35
Temperature	153(2) K
Wavelength	0.71073 Å
Crystal system	Orthorhombic
Space group	Pna21
Unit cell dimensions	a = 17.7100(5) Å $\alpha = 90^\circ$. b = 8.4320(10) Å $\beta = 90^\circ$. c = 19.4690(13) Å $\gamma = 90^\circ$.
Volume	2907.3(4) Å ³
Z	8
Density (calculated)	1.180 Mg/m ³
Absorption coefficient	0.075 mm ⁻¹
F(000)	1120
Crystal size	0.38 x 0.09 x 0.06 mm
Theta range for data collection	2.09 to 24.99°.
Index ranges	-20 ≤ h ≤ 21, -10 ≤ k ≤ 10, -23 ≤ l ≤ 23
Reflections collected	4831
Independent reflections	2635 [R(int) = 0.0990]
Completeness to theta = 24.99°	99.9 %
Absorption correction	None
Refinement method	Full-matrix least-squares on F ²
Data / restraints / parameters	2635 / 25 / 355
Goodness-of-fit on F ²	1.062
Final R indices [I > 2σ(I)]	R1 = 0.0676, wR2 = 0.1220
R indices (all data)	R1 = 0.1417, wR2 = 0.1471
Largest diff. peak and hole	0.223 and -0.187 e.Å ⁻³

Appendix B: X-Ray Data for Epimer 65

X-ray: Experiment for 65:

Crystals grew as clusters of small, colorless needles by evaporation of the mother liquor. The data crystal was cut from a cluster of crystals and had approximate dimensions; 0.19 x 0.09 x 0.08 mm. The data were collected on a Nonius Kappa CCD diffractometer using a graphite monochromator with MoK α radiation ($\lambda = 0.71073\text{\AA}$). A total of 201 frames of data were collected using ω -scans with a scan range of 1.1° and a counting time of 260 seconds per frame. The data were collected at 153 K using an Oxford Cryostream low temperature device. Details of crystal data, data collection and structure refinement are listed in Table 1. Data reduction were performed using DENZO-SMN.¹ The structure was solved by direct methods using SIR97² and refined by full-matrix least-squares on F^2 with anisotropic displacement parameters for the non-H atoms using SHELXL-97.³ The hydrogen atoms on carbon were calculated in ideal positions with isotropic displacement parameters set to 1.2xUeq of the attached atom (1.5xUeq for methyl hydrogen atoms). The hydrogen atom bound to O2 was observed in a ΔF map and refined with an isotropic displacement parameter. The absolute configuration of the molecule was assigned arbitrarily. The function, $\sum w(|F_o|^2 - |F_c|^2)^2$, was minimized, where $w = 1/[(\sigma(F_o))^2 + (0.0268*P)^2 + (0.5635*P)]$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. $R_w(F^2)$ refined to 0.144, with $R(F)$ equal to 0.0758 and a goodness of fit, S , = 1.03. Definitions used for calculating $R(F)$, $R_w(F^2)$ and the goodness of fit, S , are given below.⁴ The data were checked for secondary extinction effects but no correction was necessary. Neutral atom scattering factors and values used to calculate the linear absorption coefficient are from the International Tables for X-ray Crystallography (1992).⁵

Appendix C: X-Ray Data for γ -Hydroxy Dienone 74

X-ray Experimental for 74:

Crystals grew as colorless needles by slow evaporation from dichloromethane and hexanes. The data crystal was a long lathe that had approximate dimensions; 0.53 x 0.08 x 0.07 mm. The data were collected on a Nonius Kappa CCD diffractometer using a graphite monochromator with MoK α radiation (λ = 0.71073 Å). A total of 165 frames of data were collected using ω -scans with a scan range of 1.5° and a counting time of 108 seconds per frame. The data were collected at 153 K using an Oxford Cryostream low temperature device. Details of crystal data, data collection and structure refinement are listed in Table 1. Data reduction were performed using DENZO-SMN.¹ The structure was solved by direct methods using SIR97² and refined by full-matrix least-squares on F² with anisotropic displacement parameters for the non-H atoms using SHELXL-97.³ The hydrogen atoms on carbon were calculated in ideal positions with isotropic displacement parameters set to 1.2xUeq of the attached atom (1.5xUeq for methyl hydrogen atoms). The hydroxyl group hydrogen atoms were observed in a ΔF map and refined with isotropic displacement parameters. The function, $\Sigma w(|F_o|^2 - |F_c|^2)^2$, was minimized, where $w = 1/[(\sigma(F_o))^2 + (0.044*P)^2 + (0.2463*P)]$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. $R_w(F^2)$ refined to 0.0967, with R(F) equal to 0.0481 and a goodness of fit, S, = 1.04. Definitions used for calculating R(F), $R_w(F^2)$ and the goodness of fit, S, are given below.⁴ Neutral atom scattering factors and values used to calculate the linear absorption coefficient are from the International Tables for X-ray Crystallography (1992).⁵ All figures were generated using SHELXTL/PC.⁶ Tables of positional and thermal parameters, bond lengths and angles, torsion angles, figures and lists of observed and calculated structure factors are located in tables 1 through through 7.

Vita

Heriberto Rivera Jr. was born in Palm Springs, CA. After he was born his family returned to Mexico. After three years his family emigrated to Holtville, California where he graduated from Holtville High School in June of 2000. He went on to earn his B.Sc. in biochemistry from UCSD in 2005. Not knowing any better he made the decision to enroll in the Graduate Program at UT Austin in 2006.
